# HC-SR501 Passive Infrared (PIR) Motion Sensor

This motion sensor module uses the LHI778 Passive Infrared Sensor and the BISS0001 IC to control how motion is detected.

The module features adjustable sensitivity that allows for a motion detection range from 3 meters to 7 meters, also includes time delay adjustments and trigger selection that allow for fine tuning within your application.

HC-SR501 Pin Outs and Controls
| Pin or Control	Function
Time Delay Adjust	Sets how long the output remains high after detecting motion.... Anywhere from 5 seconds to 5 minutes.
Sensitivity Adjust	Sets the detection range.... from 3 meters to 7 meters
Trigger Selection Jumper	Set for single or repeatable triggers.
Ground pin	Ground input
Output Pin	Low when no motion is detected.. High when motion is detected. High is 3.3V
Power Pin	5 to 20 VDC Supply input

HC SR501 PIR Functional Description

The SR501 will detect infrared changes and if interpreted as motion, will set its output low.
What is or is not interpreted as motion is largely dependent on user settings and adjustments.

Device Initialization

The device requires nearly a minute to initialize.
During this period, it can and often will output false detection signals.
Circuit or controller logic needs to take this initialization period into consideration.

Device Area of Detection
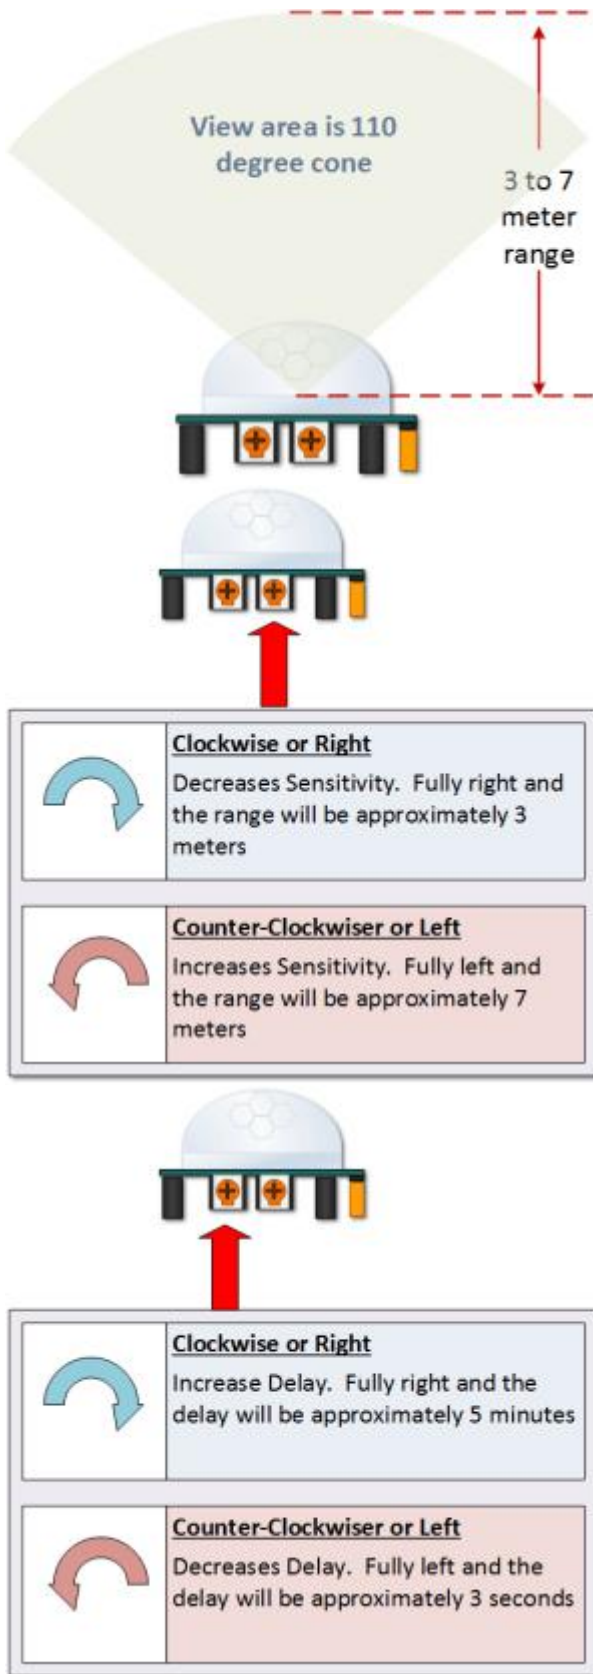

The device will detect motion inside a 110 degree cone with a range of 3 to 7 meters.

View area is 110 degree cone

3 to 7 meter range

PIR Range (Sensitivity) Adjustment

As mentioned, the adjustable range is from approximately 3 to 7 meters.

Clockwise or Right
Decreases Sensitivity. Fully right and the range will be approximately 3 meters

Counter-Clockwiser or Left
Increases Sensitivity. Fully left and the range will be approximately 7 meters

Time Delay Adjustment

The time delay adjustment determines how long the output of the PIR sensor module will remain high after detection motion. The range is from about 3 seconds to five minutes.

Clockwise or Right
Increase Delay. Fully right and the delay will be approximately 5 minutes

Counter-Clockwiser or Left
Decreases Delay. Fully left and the delay will be approximately 3 seconds

3 Seconds Off After Time Delay Completes – IMPORTANT

The output of this device will go LOW (or Off) for approximately 3 seconds AFTER the time delay completes. In other words, ALL motion detection is blocked during this three second period.

For Example:

- Imagine you're in the single trigger mode (see below) and your time delay is set 5 seconds.
  - The PIR will detect motion and set it high for 5 seconds.
  - After five seconds, the PIR will sets its output low for about 3 seconds.

- o During the three seconds, the PIR will not detect motion.
- o After three seconds, the PIR will detect motion again and detected motion will once again set the output high and the output will remain on as dictated by the Time Delay adjustment and trigger mode selection.

OVERRIDING THE TIME DELAY – If you're connecting your HC-SR501 to an Arduino,   it is likely that you are going to take some sort of action when motion is detected.   For example, you may wish to brighten lights when motion is detected and dim the lights when motion is no longer connected

Simply delay dimming within your sketch.

Trigger Mode Selection Jumper

The trigger mode selection jumper allows you to select between single and repeatable triggers.   The affect of this jumper setting is to determine when the time delay begins.

- **SINGLE TRIGGER** – The time delay begins immediately when motion is first detected.
- **REPEATABLE TRIGGER** – Each detected motion resets the time delay.   Thus the time delay begins with the last motion detected.
Single Trigger Mode – Time Delay is started immediately upon detecting motion. Continued detection is blocked

Repeatable Trigger Mode – Time Delay is re-started every time motion is detected.

HC-SR501 Dance Floor Application Examples
Imagine that you want to control lighting on a dance floor based upon where the dancers are dancing.
Understanding how the time delay and trigger mode interact will be necessary to controlling that lighting in the manner that you want.

Example One
In this first example, the time delay is set to three seconds and the trigger mode is set to single.
As you can see in the illustration below,   the motion is not always detected.
In fact, there is a period of about six seconds where motion can not be detected.

Example Two

In the next example,   the time delay is still at three seconds and the trigger is set to repeatable.   In the illustration below, you can see that the time delay period is restarted.
However, after that three seconds, detection will still be blocked for three seconds.As I mentioned previously,   you could override the 3 second blocking period with some creative code,   but do give that consideration.
Some of the electronics you use may not like an on and then off jolt. The three seconds allows for a little rest before starting back up.
Arduino HC-SR501 Motion Sensor Tutorial, connect Your Arduino to the HC-SR501
The sketch simply turns on Your Arduino LED connected to Pin 13 whenever motion is detected.
Be sure to beware of and somehow handle the 1 minute initialization in whatever application you develop.

```
// HC-SR501 Motion Detector Sample Sketch
int ledPin = 13;   // LED on Pin 13 of Arduino
int pirPin = 7; // Input for HC-S501
int pirValue; // Place to store read PIR Value
void setup() {
  pinMode(ledPin, OUTPUT);
  pinMode(pirPin, INPUT);
   digitalWrite(ledPin, LOW);
 }
void loop() {
  pirValue = digitalRead(pirPin);
   digitalWrite(ledPin, pirValue);
}
```
